PROBABILITY, SIGNALS & SYSTEMS

BY: RUAA SHALLAL ANOOZ

- In the binomial situation, each trial was independent.
 - Drawing cards from a deck and replacing the drawn card each time
- If the card is not replaced, each trial depends on the previous trial(s).
 - The hypergeometric distribution can be used in this case.

- Randomly draw *n* elements from a set of *N* elements, without replacement. Assume there are *r* successes and *N-r* failures in the *N* elements.
- The hypergeometric random variable is the number of successes, x, drawn from the r available in the n selections.

$$P(x) = \frac{\binom{r}{x}\binom{N-r}{n-x}}{\binom{N}{n}}$$

where

N = the total number of elements

r = number of successes in the N elements

n = number of elements drawn

X = the number of successes in the *n* elements

$$P(x) = \frac{\binom{r}{x}\binom{N-r}{n-x}}{\binom{N}{n}}$$

$$\mu = \frac{nr}{N}$$
$$\sigma^2 = \frac{r(N-r)n(N-n)}{N^2(N-1)}$$

States and states

1

-

E. F.

- Suppose a customer at a pet store wants to buy two hamsters for his daughter, but he wants two males or two females (i.e., he wants only two hamsters in a few months)
- If there are ten hamsters, five male and five female, what is the probability of drawing two of the same sex? (With hamsters, it's virtually a random selection.)

$$P(M=2) = P(F=2) = \frac{\binom{5}{2}\binom{10-5}{2-2}}{\binom{10}{2}} = \frac{(10)(1)}{45} = .22$$

 $P(M = 2 \text{ or } F = 2) = P(M = 2) + P(F = 2) = 2 \times .22 = .44$

IMPORTANT CONTINUOUS DISTRIBUTIONS

Normal Distribution

Undoubtedly, the most widely used model for the distribution of a random variable is a **normal distribution**.

- Central limit theorem
- Gaussian distribution

A random variable X with probability density function

$$f(x) = \frac{1}{\sqrt{2\pi\sigma}} e^{\frac{-(x-\mu)^2}{2\sigma^2}} \quad \text{for} \quad -\infty < x < \infty \tag{3-4}$$

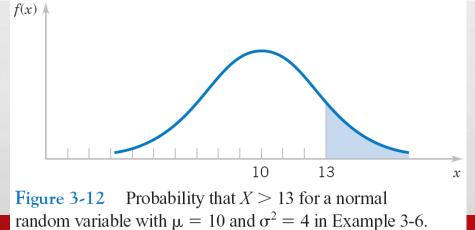

has a **normal distribution** (and is called a **normal random variable**) with parameters μ and σ , where $-\infty < \mu < \infty$, and $\sigma > 0$. Also,

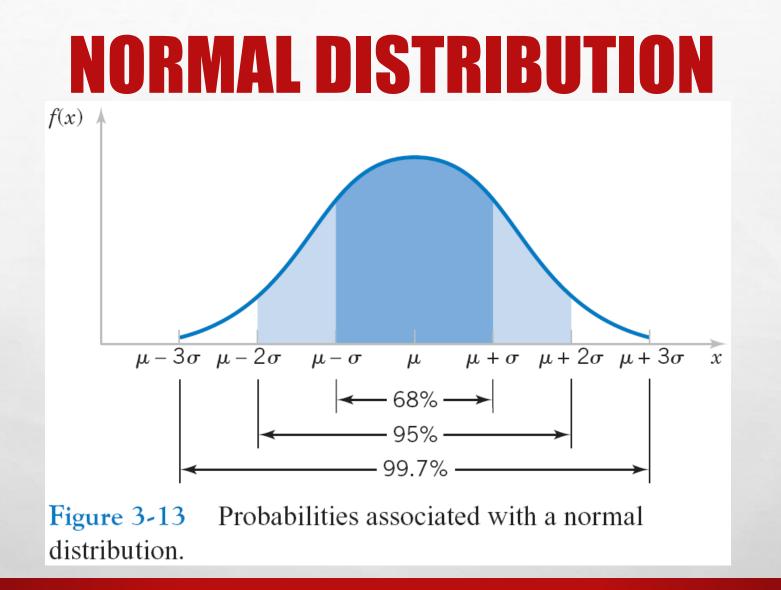

$$E(X) = \mu$$
 and $V(X) = \sigma^2$

The mean and variance of the normal distribution are derived at the end of this section.

Assume that the current measurements in a strip of wire follow a normal distribution with a mean of 10 milliamperes and a variance of 4 milliamperes². What is the probability that a measurement exceeds 13 milliamperes?

Solution. Let *X* denote the current in milliamperes. The requested probability can be represented as P(X > 13). This probability is shown as the shaded area under the normal probability density function in Fig. 3-12. Unfortunately, there is no closed-form expression for the integral of a normal pdf, and probabilities based on the normal distribution are typically found numerically or from a table (which we will introduce later).

and the

A SHALL SHALL AND A SHA

A normal random variable with $\mu = 0$ and $\sigma^2 = 1$ is called a **standard normal** random variable. A standard normal random variable is denoted as Z.

The function

$$\Phi(z) = P(Z \le z)$$

is used to denote a probability from Appendix A Table I. It is the **cumulative distribution function** of a standard normal random variable. A table (or computer software) is required because the probability can't be determined by elementary methods.

If *X* is a normal random variable with $E(X) = \mu$ and $V(X) = \sigma^2$, the random variable

$$Z = \frac{X - \mu}{\sigma}$$

is a normal random variable with E(Z) = 0 and V(Z) = 1. That is, Z is a **standard normal** random variable.

Suppose X is a normal random variable with mean μ and variance σ^2 . Then,

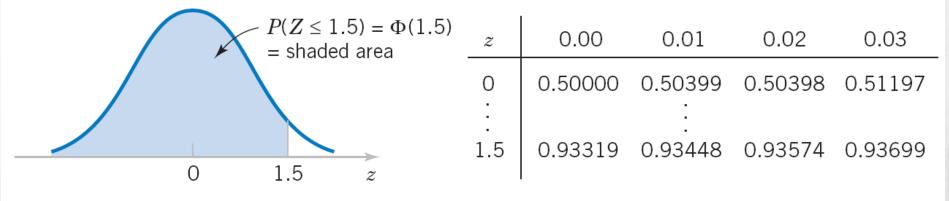

$$P(X \le x) = P\left(\frac{X - \mu}{\sigma} \le \frac{x - \mu}{\sigma}\right) = P(Z \le z)$$
(3-5)

where

Z is a standard normal random variable, and

 $z = (x - \mu)/\sigma$ is the *z*-value obtained by standardizing *x*.

The probability is obtained by entering Appendix A Table I with $z = (x - \mu)/\sigma$.

Example:

The diameter of a shaft in an optical storage drive is normally distributed with mean 0.2508 inch and standard deviation 0.0005 inch. The specifications on the shaft are 0.2500 ± 0.0015 inch. What proportion of shafts conforms to specifications?

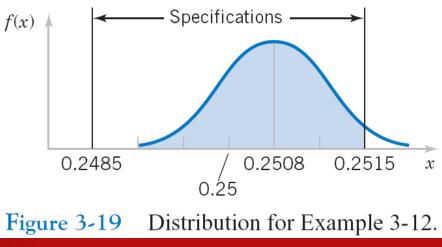

Solution. Let *X* denote the shaft diameter in inches. The requested probability is shown in Fig. 3-19 and

$$P(0.2485 < X < 0.2515) = P\left(\frac{0.2485 - 0.2508}{0.0005} < Z < \frac{0.2515 - 0.2508}{0.0005}\right)$$
$$= P(-4.6 < Z < 1.4) = P(Z < 1.4) - P(Z < -4.6)$$
$$= 0.91924 - 0.0000 = 0.91924$$

Most of the nonconforming shafts are too large, because the process mean is located very near to the upper specification limit. If the process is centered so that the process mean is equal to the target value of 0.2500,

$$P(0.2485 < X < 0.2515) = P\left(\frac{0.2485 - 0.2500}{0.0005} < Z < \frac{0.2515 - 0.2500}{0.0005}\right)$$
$$= P(-3 < Z < 3) = P(Z < 3) - P(Z < -3)$$
$$= 0.99865 - 0.00135 = 0.9973$$

By recentering the process, the yield is increased to approximately 99.73%.

UNIFORM DISTRIBUTION

p(x)

X

The uniform distribution: all values are equally likely. The uniform distribution: f(x)=1, for $1 \ge x \ge 0$

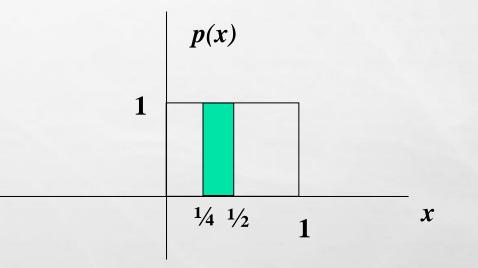

We can see it's a probability distribution because it integrates to 1 (the area under the curve is 1):

$$\int_{0}^{1} 1 = x \quad \Big|_{0}^{1} = 1 - 0 = 1$$

UNIFORM DISTRIBUTION

What's the probability that x is between $\frac{1}{4}$ and $\frac{1}{2}$?
